数论

```
初等数论
求 n 以内所有数的所有因子
vector<int> ds[N];
int main() {
    for (int i = 1; i <= n; ++i)
        for (int j = i; j \le n; j += i)
           ds[i].push_back(j);
}
整数分解
vector<ll> ifd(ll n) {
   vector<ll> v;
    for (ll d = 1; d * d <= n; ++d) {
        if (n % d) continue; v.push_back(d);
        if (d * d != n) v.push_back(n / d);
   return v;
}
质因数分解
#define W 1000001
bool ip[W]; vector<11> ps;
void sieve() {
   ps.reserve(W * 1.3 / log(W));
   memset(ip, 1, sizeof(ip)); ip[1] = 0;
    for (int i = 2; i != W; ++i) {
        if (ip[i]) ps.push_back(i);
        for (int p : ps) {
            if (i * p >= W) break;
            ip[i * p] = 0;
            if (i % p == 0) break;
    }
vector<pair<11, 11>> pfd(11 n) {
```

vector<pair<ll, 1l>> res;

```
for (ll p : ps) {
    if (p * p > n) break;
    if (n % p) continue;
    res.emplace_back(p, 0);
    do res.back().second++;
    while ((n /= p) % p == 0);
}
if (n != 1) res.emplace_back(n, 1);
return res;
}
```

二元一次不定方程

定理: ax + by = c 有解当且仅当 gcd(a,b)|c 先考虑 c = 0 的形式,此时存在无穷组形如

$$x = \frac{b}{d}t, y = -\frac{a}{d}t$$

的正整数解。

由裴蜀定理, ax + by = c 有无数组整数解。

扩展欧几里得算法可找出 ax + by = d 的一组特解 (x_0, y_0) , 这里 $d = \gcd(a, b)$ 。

// find (u,v) s.t. au+bv=gcd(a,v)
ll exgcd(ll a, ll b, ll& u, ll& v) { ll d;
 if (b) d = exgcd(b, a % b, v, u), v -= (a / b) * u;
 else d = a, u = 1, v = 0; return d;
}

于是可得所有解

$$x = \frac{cx_0 + bt}{d}, y = \frac{cy_0 - at}{d}$$

一次同余方程

定理: $ax \equiv b \mod m$ 有解当且仅当 $gcd(a, m) \mid b$

 $mathbb{M} ax \equiv b \mod m$ 等价于解二元一次不定方程 ax + km = b。

使用扩展欧几里得算法找到一组特解 (x_0,k_0) 后,易得

$$x = \frac{bx_0 + mt}{d}, k = \frac{bk_0 - at}{d}$$

即

$$x \equiv \frac{bx_0}{d} \mod \frac{m}{d}$$

```
bool lce(ll& a, ll& b, ll& p) {
    ll x, k, d = exgcd(a, p, x, k);
    if (b % d == 0) {
        a = 1; p /= d;
        b = ((x * b / d) % p + p) % p;
    }
    return a == 1;
}
```

一次同余方程组

中国剩余定理: 同余方程组

$$\left\{ \begin{array}{ll} x\equiv b_1 \mod m_1 \\ x\equiv b_2 \mod m_2 \\ & \dots \\ x\equiv b_n \mod m_n \end{array} \right.$$

有解

$$x \equiv \sum_{k=1}^{n} b_k u_k v_k \mod M$$

其中 m_i 两两互质,且

$$M = \prod_{k=1}^n m_k, u_k = \frac{M}{m_k}, u_k v_k \equiv 1 \mod m_k$$

扩展中国剩余定理 同余方程组

$$\left\{ \begin{array}{ll} x \equiv b_1 \mod m_1 \\ x \equiv b_2 \mod m_2 \end{array} \right.$$

有解当且仅当一次同余方程 $b_1 + km_1 \equiv b_2 \mod m_2$ 有解

二次剩余

勒让德符号:

$$\left(\frac{p}{q}\right) = \left\{ \begin{array}{c} 1, p \ q \\ -1, p \ q \end{array} \right.$$

(广义) 互倒定律: 若 p,q 是两个不同的奇素数,则

$$\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{\frac{p-1}{2}\frac{q-1}{2}}$$

模质数意义下的二次剩余 a 是模 p 的二次剩余当且仅当

$$a^{\frac{p-1}{2}}\equiv 1 (mod p)$$

模非质数意义下的二次剩余 a 是模 $m = \prod p_i$ 的二次剩余当且仅当 a 是模任意 p_i 的二次剩余。

模意义下的平方根 时间复杂度 $O(\log^2(p))$ 。

```
// Tonelli-Shanks algorithm. 1s~5e3
ll msqrt(ll n, ll p) {
    if (!n) return 0;
    11 q = p - 1, s = 0, z = 2;
    //while (~q & 1) q >>= 1, s++;
    q >>= (s = \_builtin\_ctzll(q));
    if (s == 1) return qpm(n, (p + 1) / 4, p);
    while(qpm(z, (p - 1) / 2, p) == 1) ++z;
    11 c = qpm(z, q, p), t = qpm(n, q, p),
      r = qpm(n, (q + 1) / 2, p), m = s;
    while(t % p != 1) {
        ll i = 1; while(qpm(t, 1ll << i, p) != 1) ++i;</pre>
        11 b = qpm(c, 111 << (m - i - 1), p);
        r = r * b % p; c = (b * b) % p;
        t = (t * c) % p; m = i;
    }
   return min(r, p - r); // r^2=(p-r)^2=n
}
解一元二次同余方程
// assert(a && isprime(p) && p > 2);
bool qce(ll a, ll b, ll c, ll p, ll& x1, ll& x2) {
    11 d = ((b * b - 4 * a * c) \% p + p) \% p;
    if (qpm(d, (p-1) / 2, p) == p-1) return false;
    d = msqrt(d, p); a = inv(2 * a % p, p);
    x1 = (p - b + d) * a % p; x2 = (2 * p - b - d) * a % p;
    return true;
高次不定方程
勾股数 高次不定方程
```

$$x^2 + y^2 = z^2$$

的所有正整数解被称为勾股数。

通过枚举 $a>b>0, \gcd(a,b)=1,2 \nmid (a+b)$ 可以获得所有本原勾股数,枚举这些勾股数的所有倍数可以获得所有勾股数。

$$\left\{ \begin{array}{lcl} x&=&2ab\\ y&=&a^2-b^2\\ z&=&a^2+b^2 \end{array} \right.$$

// Primitive Pythagorean Triple
void get() {
 11 sum = 0;
 for (ll b = 1;; ++b) {
 for (ll a = b + 1;; a += 2) {
 if (gcd(a, b) != 1) continue;
 ll x = 2 * a * b;
 ll y = a * a - b * b;
 ll z = a * a + b * b;
 //cout << x << ' ' << y << ' ' << z << endl;
 }
}</pre>

```
x^2 - dy^2 = 1
```

```
的二次不定方程。
```

```
若 d < -1 则只有 $$
```

```
bool pell_roots(ll d, ll& x, ll& y) {
    static 11 a[20000];
    double s = sqrt(d); ll m = s;
    if (m * m == d) return false;
    ll l = 0, b = m, c = 1; a[l++] = m;
    do {
        c = (d - b * b) / c;
        a[1++] = floor((s + b) / c);
        b = a[1 - 1] * c - b;
    \} while (a[1 - 1] != 2 * a[0]);
    11 p = 1, q = 0;
    for (int i = 1 - 2; i >= 0; --i)
        swap(p, q), p += q * a[i];
    if (1 \% 2) x = p, y = q;
    else x = 2 * p * p + 1, y = 2 * p * q;
    return true;
}
```

组合数取模

卢卡斯定理:

ll mbinom(ll n, ll k, ll p) {

static ll f[N];

$$\binom{n}{k} \equiv \binom{\left\lfloor \frac{n}{p} \right\rfloor}{\left\lfloor \frac{k}{p} \right\rfloor} * \binom{n \mod p}{k \mod p} \mod p$$

```
for (int i = f[0] = 1; i != p; ++i) f[i] = f[i - 1] * i % p;
    11 \text{ ans} = 1;
    do {
        if (n % p < k % p) return 0;
        ans = ans * (f[n \% p] * inv(f[k \% p] * f[(n - k) \% p], p) \% p;
        n /= p; k /= p;
    } while (n);
    return ans;
}
扩展卢卡斯定理
11 mfac(ll n, ll p, ll q) {
    if (!n) return 1;
    static map<11, vector<11>> m;
    vector<ll>& v = m[p]; if (v.empty()) v.push_back(1);
    for (int i = v.size(); i <= q; ++i)
        v.push_back(v.back() * (i % p ? i : 1) % q);
    return qpm(v[q], n / q, q) * v[n % q] % q * mfac(n / p, p, q) % q;
}
ll mbinom(ll n, ll k, ll p, ll q) {
```

```
11 c = 0;
    for (ll i = n; i; i /= p) c += i / p;
    for (ll i = k; i; i /= p) c -= i / p;
    for (ll i = n - k; i; i /= p) c -= i / p;
    return mfac(n, p, q) * inv(mfac(k, p, q), q) % q
    * inv(mfac(n - k, p, q), q) % q * qpm(p, c, q) % q;
}
11 mbinom(11 n, 11 k, 11 m) {
    vector<pair<11, 11>> ps = pfd(m);
    11 b = 0, w = 1;
    for (pair<11, 11> pp : ps) {
        ll p = pp.first, q = 1;
        while(pp.second--) q *= p;
        crt(b, w, mbinom(n, k, p, q), q);
    }
    return b;
}
原根与离散对数
原根
当模 m 乘法群为循环群时, 其生成元被称为原根。
模 m 意义下的原根存在当且仅当 m=2,4,p^t,2p^t,其中 p 为奇素数。
当 p-1 有超过一个大素因子时需要使用 Pollard's Rho 寻找原根。
ll primitive_root(ll p) {
    vector<ll> ds; ll n = p - 1;
    for (11 d = 2; d * d \le n; ++d) {
        if (n % d) continue;
        ds.push_back(d);
        while (n \% d == 0) n /= d;
    if (n != 1) ds.push_back(n);
    11 g = 1;
    while(1) {
        bool fail = 0;
        for (11 d : ds)
           if (qpm(g, (p-1) / d, p) == 1)
               fail = 1;
        if (!fail) return g; else g++;
    }
}
BSGS
解方程 a^x \equiv b \mod p, 其中 p 是质数。
复杂度 O(\sqrt{p})。
// Usage: bsgs.init(a, p); bsgs.solve(b);
struct bsgs_t {
    static const int S = 1 << 19;
    static const int msk = S - 1;
    ll a, p, m, w;
    int c, h[S], g[S], k[S], v[S];
```

```
int fin(int x) {
        for (int i = h[x & msk]; ~i; i = g[i])
            if (k[i] == x) return v[i];
        return -1;
    }
    void ins(int x, int e) {
        g[c] = h[x \& msk]; k[c] = x;
        v[c] = e; h[x \& msk] = c++;
    void init(ll a_, ll p_) {
        c = 0; a = a_{}; p = p_{}; w = 1;
        m = ceil(sqrt(p));
        memset(h, 0xff, sizeof(h));
        for (int i = 0; i != m; ++i) {
            if (fin(w) == -1) ins(w, i);
            w = w * a % p;
        assert(gcd(w, p) == 1);
        w = inv(w, p);
        //w = qpm(w, p - 2, p);
    }
    int solve(ll b) {
        for (int i = 0; i != m; ++i) {
            int r = fin(b);
            if (r != -1) return i * m + r;
            b = b * w \% p;
        }
        return -1;
    }
} bsgs;
扩展 BSGS
解方程 a^x \equiv b \mod p, a, p 任意, p = 1 可能需要特判。
复杂度 O(\sqrt{p})。
ll exbsgs(ll a, ll b, ll m) {
    if (b == 1) return 0;
    11 d, w = 1; int c = 0;
    for (ll d; (d = gcd(a, m)) != 1;) {
        if (b \% d) return -1;
        b /= d; m /= d; ++c;
        w = (w * (a / d)) % m;
        if (w == b) return c;
    }
    b = b * inv(w, m) % m;
    bsgs.init(a, m);
    11 res = bsgs.solve(b);
    return res == -1 ? -1 : res + c;
}
```

Pohlig-Hellman

解方程 $a^x \equiv b \mod p$, 其中 p 是最大质因子较小的的大质数。

```
设 p-1 = \prod_{i=1}^{n} p_i^{c_i}, 则时间复杂度为 O(\sum_{i=1}^{n} c_i \sqrt{p_i})
// Solve q^x=a
11 mlog0(11 g, 11 a, 11 p) {
    vector<pf> pfs = pfd(p - 1);
    11 x = 0, b = 1;
    for (pf f : pfs) {
        ll q = qpm(f.p, f.c, p), w = 1, t = a, r = 0;
        ll h = qpm(g, (p - 1) / f.p, p);
        bsgs.init(h, p, f.p);
        for (int i = 0; i != f.c; ++i) {
            ll z = bsgs.solve(qpm(t, (p - 1) / (w * f.p), p));
            t = mul(t, qpm(qpm(g, w * z, p), p - 2, p), p);
            r += w * z; w *= f.p;
        crt(x, b, r, q);
    return x;
}
// Solve a \hat{x}=b \pmod{p}
11 mlog(ll a, ll b, ll p) {
    11 g = primitive_root(p);
    ll u = mlog0(g, a, p), v = mlog0(g, b, p), m = p - 1;
    if (!lce(u, v, m))
        return -1;
    else
        return v;
}
素性测试与大整数分解
Miller-Rabin
// Miller-Rabin primality test(Deterministic)
// { 2, 7, 61 } for 2^32
// { 2, 3, 7, 61, 24251 } for 1e16 (except 46856248255981)

    return res;
}
积性函数与筛法
积性函数
函数 f(x) 是积性函数当且仅当 \forall a, b, \gcd(a, b) = 1, f(a)f(b) = f(ab)。
常见的积性函数:
                                          e(n) = [n == 1]
                                              1(n) = 1
                                            id^k(n) = n
ll eulerphi(ll n) {
    11 \text{ res} = 1;
    for (ll p : ps) {
        if (p * p > n) break;
        if (n % p) continue;
        n \neq p; res *= (p - 1);
        while (n \% p == 0) \{ n /= p; res *= p; \}
    if (n != 1) res *= n - 1;
    return res;
}
```

狄利克雷卷积

两个函数的狄利克雷卷积为

$$(f*g)(n) = \sum_{d|n} f(d)g(\frac{n}{d})$$

常见积性函数的卷积关系:

\$

 $e = \mu * 1$

d = 1 * 1

 $\sigma = id*1$

 $\varphi = id * \mu$

            ip[i * j] = 0;
            if (i % j) {
                // f[i * j] = (3)
```

杜教筛

目的: 求积性函数 f(x) 的前缀和 $S_f(n) = \sum_{i=1}^n f(i)$ 。

若存在积性函数 g,h 满足 f*g=h,且 S_g 与 S_h 能快速求出,则 $S_f(n)$ 能在 $O(n^{\frac{2}{3}})$ 内求出。推导:

$$S_h(n) = \sum_{i=1}^n h(i) = \sum_{i=1}^n \sum_{d|i} g(d) f(\frac{i}{d}) = \sum_{d=1}^n g(d) \sum_{d|i \wedge i \leq n} f(\frac{i}{d}) = \sum_{d=1}^n g(d) \sum_{j=1}^{\lfloor \frac{n}{d} \rfloor} f(j) = \sum_{d=1}^n g(d) S_f(\left\lfloor \frac{n}{d} \right\rfloor)$$

右式可数论分块,用线性筛法处理出前 $n^{\frac{2}{3}}$ 个 $S_f(n)$ 可将复杂度降至 $O(n^{\frac{2}{3}})$ 。 常见的 f 与 g 和 h。

f	g	h	推导
$\overline{i^k\varphi(i)}$	id^k	id^{k+1}	
			$\sum_{d n} d^k \left(\frac{n}{d}\right)^k \varphi(\frac{n}{d}) = n^k \sum_{d n} \varphi(\frac{n}{d}) = n^{k+1}$

```

min25 筛

目的: 求积性函数 f(x) 的前缀和 $S_f(n) = \sum_{i=1}^n f(i)$ 。

若 f(p) 可以表达为关于 p 的简单多项式且 $f(p^e)$ 可以快速求,则可以在 $O(\frac{n^{\frac{3}{4}}}{\log n})$ 内求出 $S_f(n)$ 。 定义:

- $1. p_i$ 表示第 i 个质数。
- $2. m_i$ 表示 i 的最小质因子。
- 3. e_i 表示 i 的最小质因子在 i 中的幂次。

共分两步,求出 $g_k(n) = \sum_{n \le n} p_i^k$,再用 $g_k(n)$ 求出 $S_f(n)$ 。

预处理 预处理出 $k > \sqrt{n}$ 时 k 被映射至的位置。

预处理出 $m \leq \sqrt{n}$ 时所有的 $s_k(m) = \sum_{i=1}^m p_i^k$

第一步:求出 $g_k(n)$ 观察到 i^k 是完全积性函数,考虑利用完全积性筛出 $g_k(n)$,即一步步把最小质因子为某个质数的数的 k 次方筛掉。

定义 $g_k(n,j)$ 表示筛掉了最小质因子小于等于 p_i 的所有 i^k 后余下所有 i^k 的和(只筛合数不筛质数)。也可写作

$$g_k(n,j) = \sum_{i=1}^j p_i^k + \sum_{i \leq n, m_i > p_j} i^k$$

我们要求的 $g_k(n) = g_k(n, \infty)$ 。经过简单推导可以得到:

$$g_k(n,j) = \left\{ \begin{array}{ll} g_k(n,j-1) & p_j > \sqrt{n} \\ g_k(n,j-1) - p_j^k \left(g_k(\lfloor \frac{n}{p_j} \rfloor, j-1) - s_k(j)\right) & p_j \leq \sqrt{n} \\ \sum_{i=1}^n i^k & j = 0 \end{array} \right.$$

注:第 j 步筛掉的是所有最小质因子为 p_j 的合数的 k 次方之和。在第 j-1 步的基础上,所有 n 以内的最小质因子为 p_j 的合数在除以 p_j 后余下部分的 k 次方之和即为 $g(\lfloor \frac{n}{p_j} \rfloor, j-1)$ 减去未被筛去的小于 p_j 的质数的 k 次方之和。

第二步: 求出 $S_f(n)$ 这一步需要将 f(n) 在第一步中筛去的在合数位置的取值按相反的顺序加回来。

定义 S(n,j) 为将最小质因子小于等于 p_j 的合数位置上的取值筛去后的 $S_f(n)$, 即

$$S(n,j) = \sum_{i \leq n, m_i > p_j} f(i)$$

枚举所有最小质因子大于等于 p_{j} 且最小质因子形如 p_{k}^{e} 的数

$$S(n,j) = \sum_{k>j} \sum_{e} f(p_k^e) \left(1 + S(\lfloor \frac{n}{p_k^e} \rfloor, k+1) \right)$$

最终所求即为 S(n,0)。

```

$$f(k_1,k_2,a,b,c,n) = \sum_{r=0}^n x^{k_1} \left\lfloor \frac{ax+b}{c} \right\rfloor^{k_2}$$

若 $a \ge c$ 或 $b \ge c$, 令 $a = q_a c + r_a$, $b = q_b c + r_b$

$$f(k_1, k_2, a, b, c, n) = \sum_{x=0}^{n} x^{k_1} \left(\left\lfloor \frac{r_a x + r_b}{c} \right\rfloor + q_a x + q_b \right)^{k_2}$$

$$= \sum_{i=0}^{k_2} {k_2 \choose i} \sum_{x=0}^{n} x^{k_1} \left\lfloor \frac{r_a x + r_b}{c} \right\rfloor^{k_2 - i} (q_a x + q_b)^i$$

$$= \sum_{i=0}^{k_2} {k_2 \choose i} \sum_{j=0}^{i} {i \choose j} q_a^j q_b^{i-j} \sum_{x=0}^{n} x^{k_1 + j} \left\lfloor \frac{r_a x + r_b}{c} \right\rfloor^{k_2 - i}$$

$$= \sum_{i=0}^{k_2} \binom{k_2}{i} \sum_{j=0}^i \binom{i}{j} q_a^j q_b^{i-j} f(k_1+j,k_2-i,r_a,r_b,c,n)$$

若
$$a=0$$

$$f(k_1, k_2, a, b, c, n) = \sum_{x=0}^{n} x^{k_1} \left\lfloor \frac{b}{c} \right\rfloor^{k_2} = \left\lfloor \frac{b}{c} \right\rfloor^{k_2} \sum_{x=0}^{n} x^{k_1}$$

若
$$k_2 = 0$$

$$f(k_1,k_2,a,b,c,n) = \sum_{r=0}^n x^{k_1}$$

若 $an+b \le c$

$$f(k_1, k_2, a, b, c, n) = 0$$

否则有 $a \le c$ 且 $b \le c$, 进行代换

$$w^{k_2} = \sum_{y=0}^{w-1} \left((y+1)^{k_2} - y^{k_2} \right)$$

$$f(k_1,k_2,a,b,c,n) = \sum_{x=0}^n x^{k_1} \sum_{y=0}^{\left \lfloor \frac{ax+b}{c} \right \rfloor - 1} ((y+1)^{k_2} - y^{k_2})$$

杂项

大整数相乘取模

```
typedef unsigned long long ull;
typedef long double ld;
ull mul(ull a, ull b, ull p) {
    ll res = a * b - p * (ull)((ld)a * (ld)b / (ld)M);
    return res + p * (res < 0) - p * (ret >= (ll)p);
}
```

完全数

偶完全数据有形式 $2^{n-1}(2^n-1)$, 目前未发现奇完全数。

反素数

```
// 求在因子数最多的前提下最小的数 x
```

```
pair<11, 11> dfs(11 n, int c, int i, 11 a, 11 b) {
    if (i == 12) return { -a, b };
    else {
        int p = ps[i]; 11 q = 1;
        pair<11, 11> res = { 0, 0 };
        for (int e = 0; e <= c && n / q; ++e, q *= p)
            res = min(res, dfs(n / q, e, i + 1, a * (e + 1), b * q));
        return res;
    }
